Application Model:

An application model is a graphical representation of an application, and the relationship of the infrastructure components that are required to support or provide functionality to the application.

Our Application will give a source code and config file to the platform.

Config file details will contain the list of sensors which they want to use.

Then If the user wants to deploy the platform manager will then call the scheduler which in turn will call the deployer.

The deployer will run the application on of the nodes then the user will now interact with the application.
